# Problem Solutions

e-Chapter 7

*Pierre Paquay*

## Problem 7.1

To solve this problem, we first begin by separating the positive decision region into two components : the lower one corresponding to $x_2 \in [-1, 1]$ and the upper one corresponding to $x_2 \in [1, 2]$. To define the decision region, we need 7 perceptrons, namely

$$h_1(x) = \text{sign}(x_2 - 2), \ h_2(x) = \text{sign}(x_2 - 1), \ h_3(x) = \text{sign}(x_2 + 1),$$

for the horizontal lines, and

$$h_4(x) = \text{sign}(x_1 + 2), \ h_5(x) = \text{sign}(x_1 + 1), \ h_6(x) = \text{sign}(x_1 - 1), \ h_7(x) = \text{sign}(x_1 - 2)$$

for the vertical lines. We are now able to define the lower decision region by $\overline{h_2}h_3h_4\overline{h_7}$, and the upper decision region by $\overline{h_1}h_2h_5\overline{h_6}$, which means that the total decision region is defined by

$$f = \overline{h_2}h_3h_4\overline{h_7} + \overline{h_1}h_2h_5\overline{h_6}$$

which actually characterizes a 3-layer perceptron.

## Problem 7.2

$(a)$ Let $x$ and $x'$ be two points from the same region. If we consider a set of $M$ hyperplanes defined by $\{x : w_i^T x = 0\}$, we have that

$$(\text{sign}(w_1^T x), \cdots, \text{sign}(w_M^T x)) = (\text{sign}(w_1^T x'), \cdots, \text{sign}(w_M^T x'));$$

or put more simply that $\text{sign}(w_i^T x) = \text{sign}(w_i^T x') = s_i$ for $i = 1, \cdots, M$ where $s_i = \pm 1$. We begin by the case where $s_i = 1$. Here, we know that $w_i^T x > 0$ and $w_i^T x' > 0$, consequently we have that, for $\lambda \in [0, 1]$,

$$w_i^T(\lambda x + (1 - \lambda)x') = \lambda w_i^T x + (1 - \lambda)w_i^T x' > 0$$

and

$$\text{sign}(w_i^T(\lambda x + (1 - \lambda)x')) = 1.$$

Now, we consider the case where $s_i = -1$. Here, we know that $w_i^T x < 0$ and $w_i^T x' < 0$, consequently we have that, for $\lambda \in [0, 1]$,

$$w_i^T(\lambda x + (1 - \lambda)x') = \lambda w_i^T x + (1 - \lambda)w_i^T x' < 0$$

and

$$\text{sign}(w_i^T(\lambda x + (1 - \lambda)x')) = -1.$$

So, in conclusion, the region is actually convex.

$(b)$ A region is defined as the following set

$$\{x : (\text{sign}(w_1^T x), \cdots, \text{sign}(w_M^T x)) = (s_1, \cdots, s_M); s_i \in \{-1, 1\}\};$$

thus a region is characterized by a particular $M$-uple $(s_1, \cdots, s_M)$. Since there are at most $2^M$ of such $M$-uples, we have at most $2^M$ different regions.

$(c)$ Let $B(N, d)$ be the maximum number of regions created by $M$ hyperplanes in $d$-dimensional space. Now, consider adding an $(M + 1)$th hyperplane; this hyperplane can obviously be viewed as a $(d - 1)$-dimensional

space, so if we project the initial $M$ hyperplanes into this space, we obtain $M$ hyperplanes in a $(d-1)$-dimensional space. These hyperplanes can create at most $B(M, d-1)$ regions in this space, and for each of these regions, we get two regions in the original $d$-dimensional space. Thus, this means that the $(M+1)$th hyperplane intersects at most $B(M, d-1)$ of the regions created by the $M$ hyperplanes in the $d$-dimensional space, and so

$$B(M+1, d) \leq B(M, d) + B(M, d-1).$$

Now, we will prove that

$$B(M, d) \leq \sum_{i=0}^{d} \binom{M}{i}$$

by induction. We begin by evaluating the boundary conditions, we have

$$B(M, 1) = M + 1 \leq \sum_{i=0}^{1} \binom{M}{i} = \binom{M}{0} + \binom{M}{1} = M + 1$$

for all $M$, and

$$B(1, d) = 2 \leq \sum_{i=0}^{d} \binom{1}{i} = \binom{1}{0} + \binom{1}{1} = 2$$

for all $d$. Now, we assume the statement is true for $M = M_0$ and all $d$, we will prove that the statement is still true for $M = M_0 + 1$ and all $d$. We have that

$$
\begin{aligned}
B(M_0 + 1, d) \quad &\leq \quad B(M_0, d) + B(M_0, d-1) \\
&\leq \quad \sum_{i=0}^{d} \binom{M_0}{i} + \sum_{i=0}^{d-1} \binom{M_0}{i} \\
&= \quad \binom{M_0}{0} + \sum_{i=1}^{d} \binom{M_0}{i} + \sum_{i=1}^{d} \binom{M_0}{i-1} \\
&= \quad 1 + \sum_{i=1}^{d} \underbrace{\left[ \binom{M_0}{i} + \binom{M_0}{i-1} \right]}_{=\binom{M_0+1}{i}} \\
&= \quad \sum_{i=0}^{d} \binom{M_0+1}{i}.
\end{aligned}
$$

We have thus proved the induction step, so the statement is true for all $M$ and $d$.

## Problem 7.3

We begin by proving the following equivalence relation

$$h_m(x) = c_m \Leftrightarrow h_m^{c_m}(x) = +1.$$

The condition is necessary because if $c_m = +1$, we have

$$h_m^{c_m}(x) = h_m(x) = c_m = +1;$$

and if $c_m = -1$, we have

$$h_m^{c_m}(x) = \overline{h}_m(x) = \overline{c}_m = +1.$$

Now the condition is also sufficient because if $c_m = +1$, we have

$$+1 = h_m^{c_m}(x) = h_m(x),$$

which means that $h_m(x) = +1 = c_m$; and if $c_m = -1$, we have

$$+1 = h_m^{c_m}(x) = \overline{h}_m(x),$$

which implies that $h_m(x) = -1 = c_m$.

Now we are able to write that

$$
\begin{aligned}
& x \in r \\
\Leftrightarrow \quad & (h_1(x), \cdots, h_M(x)) = (c_1, \cdots, c_M) \\
\Leftrightarrow \quad & h_m^{c_m}(x) = +1, \ \forall m \\
\Leftrightarrow \quad & \prod_{m=1}^{M} h_m^{c_m}(x) = +1 \\
\Leftrightarrow \quad & t_r(x) = +1.
\end{aligned}
$$

The above relation also implies that

$$x \notin r \Leftrightarrow t_r(x) = -1.$$

Now if $x$ is in a positive region ($f(x) = +1$), we know that there exists $i$ such that $x \in r_i$, and consequently that $t_{r_i}(x) = +1$ which means that

$$t_{r_1}(x) + \cdots + t_{r_k}(x) = +1 = f(x).$$

And if $x$ is in a negative region ($f(x) = -1$), we know that $x \notin r_i$ for all $i$, so $t_{r_i}(x) = -1$ for all $i$ which means that

$$t_{r_1}(x) + \cdots + t_{r_k}(x) = -1 = f(x).$$

## Problem 7.4

Since $f = t_{r_1} + \cdots + t_{r_k}$, we may write that

$$f = \text{sign}(k - \frac{1}{2} + \sum_{i=1}^{k} t_{r_i}),$$

which characterizes the penultimate layer of our perceptron. For the layer before, we have that $t_{r_i} = h_1^{c_1^{(i)}} \cdots h_M^{c_M^{(i)}}$, and consequently

$$t_{r_i} = \text{sign}(-M + \frac{1}{2} + \sum_{m=1}^{M} h_m^{c_m^{(i)}});$$

moreover, the previous layer may be characterized with

$$h_m^{c_m^{(i)}} = \text{sign}(c_m^{(i)} w_m^T x).$$

Putting all this together, we obtain the following characterization of a 3-layer perceptron

$$f = \text{sign}(k - \frac{1}{2} + \sum_{i=1}^{k} \text{sign}(-M + \frac{1}{2} + \sum_{m=1}^{M} \text{sign}(c_m^{(i)} w_m^T x)))$$

whose structure is given by $[d, kM, k, 1]$.

**Problem 7.5**

First, we decompose the unit hypercube $[0,1]^d$ into $1/\epsilon^d$ $\epsilon$-hypercubes (hypercube whose sides have length equal to $\epsilon$), thus we get a grid-like structure of our unit hypercube. Now, if we consider a decision region (which may be composed by disconnected regions) whose boundary surfaces are smooth, this decision region partition the unit hypercube into two regions : one labelled $+1$ and one labelled $-1$. We now have $k_\epsilon$ $\epsilon$-hypercubes labelled $+1$ which are formed by $2d$ hyperplanes each defined by $h_m^{(i)} = \text{sign}(w_m^{(i),T} x)$ where $m = 1, \cdots, 2d$ and $i = 1, \cdots, k_\epsilon$. So, the first layer whose task is to activate the hyperplanes involved in the positive $\epsilon$-hypercubes is characterized by

$$h_m^{(i)} = \text{sign}(w_m^{(i),T} x).$$

Now to activate the positive $\epsilon$-hypercubes $H_i$ themselves we characterize the second layer by

$$t_{H_i} = (h_1^{(i)})^{c_1^{(i)}} \cdots (h_{2d}^{(i)})^{c_{2d}^{(i)}},$$

where the $c_m^{(i)}$ are defined as in Problem 7.3 and 7.4; or

$$t_{H_i} = \text{sign}(-2d + \frac{1}{2} + \sum_{m=1}^{2d} (h_m^{(i)})^{c_m^{(i)}}).$$

And finally to activate all the positive $\epsilon$-hypercubes, we define the MLP output $h$ by

$$h = t_{H_1} + \cdots + t_{H_{k_\epsilon}};$$

or

$$h = \text{sign}(k_\epsilon - \frac{1}{2} + \sum_{i=1}^{k_\epsilon} t_{H_i}).$$

Putting all this together, we obtain the following characterization of a 3-layer perceptron

$$h = \text{sign}(k_\epsilon - \frac{1}{2} + \sum_{i=1}^{k_\epsilon} \text{sign}(-2d + \frac{1}{2} + \sum_{m=1}^{2d} \text{sign}(c_m^{(i)} w_m^{(i),T} x))).$$

Now, it remains to see that the above MLP can aribtrarily closely approximate the initial positive decision region $D_+$ (and consequently the negative decision region also); to do so, we first note that

$$\text{Vol}(H_i) = \epsilon^d \rightarrow 0 \text{ and } k_\epsilon \rightarrow \infty$$

when $\epsilon \rightarrow 0$. So, the $\epsilon$-hypercubes can be made arbitrarily small, which obviously means that the total volume of the positive $\epsilon$-hypercubes can be made arbitrarily close to the volume of the positive decision region (because of its smoothness). Mathematically, we may write that

$$\text{Vol}(H_1 \cup \cdots \cup H_{k_\epsilon}) = \sum_{i=1}^{k_\epsilon} \epsilon^d \rightarrow \text{Vol}(D_+)$$

when $\epsilon \rightarrow 0$. This means that the region where our 3-layer perceptron will output $+1$ (resp. $-1$) converges to the positive (resp. negative) decision region in our unit hypercube.

**Problem 7.6**

For a specific layer $l$, if we replace the weight $w_{ij}^{(l)}$ with $w_{ij}^{(l)} + \epsilon$, we need to recompute the corresponding node output of that layer and also the node outputs for the subsequent layers (which are the ones numbered from $l + 1$ to $L$). Consequently, for each weight $w_{ij}^{(l)}$, we have

$$\sum_{k=l+1}^{L} d^{(l)}(d^{(l-1)} + 1) + 1 + \sum_{k=l+1}^{L} d^{(l)}$$

multiplications and $\theta$-evaluations respectively; this means that the computational complexity of obtaining the partial derivatives is overall equal to

$$2\underbrace{\sum_{l=1}^{L} d^{(l)}(d^{(l-1)}+1)}_{=|W|}\left(\sum_{k=l+1}^{L} d^{(l)}(d^{(l-1)}+1)+1+\sum_{k=l+1}^{L} d^{(l)}\right)$$

$$\leq \quad 2|W|\left(\underbrace{\sum_{k=1}^{L} d^{(l)}(d^{(l-1)}+1)}_{=|W|}+1+\sum_{k=1}^{L}\underbrace{d^{(l)}}_{\leq d^{(l)}(d^{(l-1)}+1)}\right)$$

$$\leq \quad 2|W|(2|W|+1) = O(|W|^2)$$

since we need to compute the derivatives corresponding to $w_{ij}^{(l)} + \epsilon$ and also to $w_{ij}^{(l)} - \epsilon$.

## Problem 7.7

($a$) We know that

$$E_{in} = \frac{1}{N}\sum_{i=1}^{N} ||y_i - \hat{y}_i||^2,$$

and also that

$$(Y - \hat{Y})(Y - \hat{Y})^T = \begin{pmatrix} y_1^T - \hat{y}_1^T \\ \vdots \\ y_N^T - \hat{y}_N^T \end{pmatrix}(y_1 - \hat{y}_1, \cdots, y_N - \hat{y}_N) = \begin{pmatrix} ||y_1 - \hat{y}_1||^2 & * & * \\ & * & \ddots & * \\ * & * & ||y_N - \hat{y}_N||^2 \end{pmatrix}.$$

Consequently, we get that

$$E_{in} = \frac{1}{N}\text{trace}((Y - \hat{Y})(Y - \hat{Y})^T).$$

($b$) We may write that

$$E_{in} = \frac{1}{N}\text{trace}(YY^T - ZVY^Y - YV^TZ^T + ZVV^TZ^T)$$

$$= \frac{1}{N}\text{trace}(YY^T - 2ZVY^T + ZVV^TZ^T),$$

since $\text{trace}(A) = \text{trace}(A^T)$. We are now ready to compute the derivatives, we have

$$\frac{\partial E_{in}}{\partial V} = \frac{1}{N}(-2\underbrace{\frac{\partial \text{trace}(ZVY^T)}{\partial V}}_{=Z^TY} + \underbrace{\frac{\partial \text{trace}(ZVV^TZ^T)}{\partial V}}_{=Z^TZV+Z^TZV=2Z^TZV})$$

$$= \frac{1}{N}(2Z^TZV - 2Z^TY),$$

because of the following identities

$$\frac{\partial \text{trace}(AXB)}{\partial X} = A^TB^T \text{ and } \frac{\partial \text{trace}(AXX^TB)}{\partial X} = BAX + A^TB^TX.$$

5

We also have

$$E_{in}$$
$$= \frac{1}{N}\mathrm{trace}(YY^T - 2(V_0 + \theta(XW)V_1)Y^T + (V_0 + \theta(XW)V_1)(V_0^T + V_1^T\theta(XW)^T)$$
$$= \frac{1}{N}\mathrm{trace}(YY^T - 2V_0Y^T - 2\theta(XW)V_1Y^T + V_0V_0^T + V_0V_1^T\theta(XW)^T + \theta(XW)V_1V_0^T + \theta(XW)V_1V_1^T\theta(XW)^T)$$
$$= \frac{1}{N}\mathrm{trace}(YY^T - 2V_0Y^T - 2\theta(XW)V_1Y^T + V_0V_0^T + 2\theta(XW)V_1V_0^T + V_1V_1^T\theta(XW)^T\theta(XW)),$$

since the trace can be permuted in a cycle and $\mathrm{trace}(A) = \mathrm{trace}(A^T)$. The other derivative may be written as

$$\frac{\partial E_{in}}{\partial W} = \frac{1}{N}(-2\frac{\partial\mathrm{trace}(\theta(XW)V_1Y^T)}{\partial W} + 2\frac{\partial\mathrm{trace}(\theta(XW)V_1V_0^T)}{\partial W} + \frac{\partial\mathrm{trace}(V_1V_1^T\theta(XW)^T\theta(XW))}{\partial W})$$
$$= \frac{1}{N}(-2X^T\theta'(XW) \otimes YV_1^T + 2X^T\theta'(XW) \otimes V_0V_1^T + X^T(\theta'(XW) \otimes [\theta(XW)2V_1V_1^T])$$
$$= 2X^T[\theta'(XW) \otimes (-YV_1^T + V_0V_1^T + \theta(XW)V_1V_1^T)]$$

because of the following identities

$$\frac{\partial\mathrm{trace}(\theta(BX)A)}{\partial X} = B^T\theta'(BX) \otimes A^T \text{ and } \frac{\partial\mathrm{trace}(A\theta(BX)^T\theta(BX))}{\partial X} = B^T[\theta'(BX) \otimes (\theta(BX)(A + A^T))].$$

## Problem 7.8

($a$) By hypothesis, we know that $\{\eta_1, \eta_2, \eta_3\}$ with $\eta_1 < \eta_2 < \eta_3$ is an U-arrangement which means that

$$E(\eta_2) < \min\{E(\eta_1), E(\eta_3)\}.$$

Since $E(\eta)$ is a quadratic curve, we know that it is decreasing (resp. increasing) to the left (resp. right) of its minimum $\bar{\eta}$. So if we assume that $\bar{\eta} < \eta_1$, we get that $E(\eta_1) \le E(\eta_2) \le E(\eta_3)$ which is impossible by definition of an U-arrangement; and if we assume that $\bar{\eta} > \eta_3$, we get that $E(\eta_1) \ge E(\eta_2) \ge E(\eta_3)$ which is also impossible by definition of an U-arrangement. Consequently, we have $\bar{\eta} \in [\eta_1, \eta_3]$.

($b$) First, we solve the linear system in $a$, $b$, and $c$ below

$$\begin{cases} E(\eta_1) &= a\eta_1^2 + b\eta_1 + c = e_1 \\ E(\eta_2) &= a\eta_2^2 + b\eta_2 + c = e_2 \\ E(\eta_3) &= a\eta_3^2 + b\eta_3 + c = e_3 \end{cases}.$$

Let $D$ be the determinant of the system, which is

$$D = \begin{vmatrix} \eta_1^2 & \eta_1 & 1 \\ \eta_2^2 & \eta_2 & 1 \\ \eta_3^2 & \eta_3 & 1 \end{vmatrix},$$

where $D \neq 0$ since $\eta_1 < \eta_2 < \eta_3$; now we easily get that

$$a = \begin{vmatrix} e_1 & \eta_1 & 1 \\ e_2 & \eta_2 & 1 \\ e_3 & \eta_3 & 1 \end{vmatrix}/D = \frac{(e_1 - e_2)(\eta_1 - \eta_3) - (e_1 - e_3)(\eta_1 - \eta_2)}{D}$$

and

$$b = \begin{vmatrix} \eta_1^2 & e_1 & 1 \\ \eta_2^2 & e_2 & 1 \\ \eta_3^2 & e_3 & 1 \end{vmatrix} / D = \frac{-(e_1 - e_2)(\eta_1^2 - \eta_3^2) + (e_1 - e_3)(\eta_1^2 - \eta_2^2)}{D}.$$

Since the minimum of such a quadratic function is given by $-b/2a$, we finally get

$$\bar{\eta} = \frac{1}{2} \left[ \frac{(e_1 - e_2)(\eta_1^2 - \eta_3^2) - (e_1 - e_3)(\eta_1^2 - \eta_2^2)}{(e_1 - e_2)(\eta_1 - \eta_3) - (e_1 - e_3)(\eta_1 - \eta_2)} \right].$$

($c$) We enumerate the four cases below.

1. If $\bar{\eta} < \eta_2$ :

   - If $E(\bar{\eta}) < E(\eta_2)$, then $\{\eta_1, \bar{\eta}, \eta_2\}$ is a new U-arrangement.
   - If $E(\bar{\eta}) > E(\eta_2)$, then $\{\bar{\eta}, \eta_2, \eta_3\}$ is a new U-arrangement.

2. If $\bar{\eta} > \eta_2$ :

   - If $E(\bar{\eta}) < E(\eta_2)$, then $\{\eta_2, \bar{\eta}, \eta_3\}$ is a new U-arrangement.
   - If $E(\bar{\eta}) > E(\eta_2)$, then $\{\eta_1, \eta_2, \bar{\eta}\}$ is a new U-arrangement.

($d$) If $\bar{\eta} = \eta_2$, by continuity we are always able to find another $\eta_2'$ close to $\eta_2$ such that

$$E(\eta_2') < \min\{E(\eta_1), E(\eta_3)\}.$$

In this case, we can use this new $\eta_2'$ in place of $\eta_2$ and proceed with the algorithm.

## Problem 7.9

($a$) Since $w$ is uniformly sampled in the unit cube, we may write that

$$
\begin{aligned}
\mathbb{P}[E(w) \le E(w^*) + \epsilon] &= \mathbb{P}\left[ \frac{1}{2}(w - w^*)^T H (w - w^*) \le \epsilon \right] \\
&= \int_{(w - w^*)^T H (w - w^*) \le 2\epsilon} dw_1 \cdots dw_d \\
&= \int_{x^T H x \le 2\epsilon} \underbrace{|\det \frac{\partial w}{\partial x}|}_{=1} dx_1 \cdots dx_d
\end{aligned}
$$

where we have made the change of variables $x = w - w^*$. As $H$ is positive definite and symmetric, we know that there exists an orthogonal matrix $A$ such that $H = A\mathrm{diag}(\lambda_1^2, \cdots, \lambda_d^2)A^T$. Thus, if we use $y = A^T x$ as a change of variables, we now get that

$$
\begin{aligned}
\mathbb{P}[E(w) \le E(w^*) + \epsilon] &= \int_{x^T H x \le 2\epsilon} dx_1 \cdots dx_d \\
&= \int_{y^T \mathrm{diag}(\lambda_1^2, \cdots, \lambda_d^2) y \le 2\epsilon} \underbrace{|\det \frac{\partial x}{\partial y}|}_{=|A|=1} dy_1 \cdots dy_d.
\end{aligned}
$$

We now use a third change of variables $z = \mathrm{diag}(\lambda_1, \cdots, \lambda_d)y$, in this case we obtain

7

$$\mathbb{P}[E(w) \leq E(w^*) + \epsilon] = \int_{y^T \mathrm{diag}(\lambda_1^2, \cdots, \lambda_d^2)y \leq 2\epsilon} dy_1 \cdots dy_d$$

$$= \int_{z^T z \leq 2\epsilon} \underbrace{|\det \frac{\partial y}{\partial z}|}_{= \frac{1}{|\lambda_1 \cdots \lambda_d|} = \frac{1}{\sqrt{\det H}}} dz_1 \cdots dz_d$$

$$= \frac{1}{\sqrt{\det H}} \int_{z^T z \leq 2\epsilon} dz_1 \cdots dz_d = \frac{S_d(2\epsilon)}{\sqrt{\det H}}.$$

($b$) It is clear that

$$\mathbb{P}[E(w_{min}) > E(w^*) + \epsilon] = \mathbb{P}[(E(w_1) > E(w^*) + \epsilon) \cap \cdots \cap (E(w_N) > E(w^*) + \epsilon)]$$

$$= \prod_{i=1}^{N} \mathbb{P}[E(w_1) > E(w^*) + \epsilon]$$

$$= (1 - \mathbb{P}[E(w_1) \leq E(w^*) + \epsilon])^N$$

$$= \left(1 - \frac{S_d(2\epsilon)}{\sqrt{\det H}}\right)^N.$$

We may write that

$$S_d(2\epsilon) = \frac{\pi^{d/2}(2\epsilon^d)}{\Gamma(d/2+1)} \approx \frac{1}{\sqrt{\pi d}} \left(\frac{8e\pi}{d}\right)^{d/2} \epsilon^d,$$

moreover, we also have that

$$\bar{\lambda}^d = \det H.$$

Consequently, we may write that

$$\mathbb{P}[E(w_{min}) > E(w^*) + \epsilon] = \left(1 - \frac{S_d(2\epsilon)}{\sqrt{\det H}}\right)^N$$

$$\approx \left(1 - \frac{1}{\sqrt{\pi d}} \underbrace{\left(\frac{8e\pi}{\bar{\lambda}}\right)^{d/2}}_{\approx \mu^d} \left(\frac{\epsilon^d}{d^{d/2}}\right)\right)^N$$

$$\approx \left(1 - \frac{1}{\sqrt{\pi d}} \left(\frac{\mu\epsilon}{\sqrt{d}}\right)^d\right)^N.$$

($c$) From point ($b$), we know that

$$\mathbb{P}[E(w_{min}) > E(w^*) + \epsilon] \approx \left(1 - \frac{1}{\sqrt{\pi d}} \left(\frac{\mu\epsilon}{\sqrt{d}}\right)^d\right)^N$$

$$\approx e^{N \ln(1 - \frac{1}{\sqrt{\pi d}}(\frac{\mu\epsilon}{\sqrt{d}})^d)}$$

$$\approx e^{-N \frac{1}{\sqrt{\pi d}}(\frac{\mu\epsilon}{\sqrt{d}})^d}$$

$$\approx e^{\frac{1}{\sqrt{\pi d}} \log \eta}$$

because we have

$$-N\frac{1}{\sqrt{\pi d}}\left(\frac{\mu\epsilon}{\sqrt{d}}\right)^d \approx \frac{1}{\sqrt{\pi d}}\log\eta.$$

In conclusion, we get that

$$\mathbb{P}[E(w_{min}) > E(w^*) + \epsilon] \approx \eta^{\frac{1}{\sqrt{\pi d}}} \geq \eta$$

since $0 \leq \eta \leq 1$; thus we may now write that

$$\mathbb{P}[E(w_{min}) \leq E(w^*) + \epsilon] \leq 1 - \eta.$$

## Problem 7.10

If we initialize all weights to 0, we have $W^{(l)} = 0$ for $l = 1, \cdots, L$. Consequently, we have that

$$s^{(l)} = (W^{(l)})^T x^{(l-1)} = 0$$

as well; so we get

$$x^{(l)} = \theta(s^{(l)}) = \theta(0) = \tanh(0) = 0$$

for $l = 1, \cdots, L$. This impacts the gradient in the following way, we may write

$$\frac{\partial e}{\partial W^{(l)}} = x^{(l-1)}(\delta^{(l)})^T = 0$$

for $l = 2, \cdots, L$. To see what happens when $l = 1$, we first note that

$$\delta_j^{(1)} = \theta'(s_j^{(1)}) \sum_{k=1}^{d^{(2)}} \underbrace{w_{jk}^{(2)}}_{=0} \delta_k^{(2)} = 0$$

for all $j$; which means that $\partial e/\partial W^{(1)} = 0$. In conclusion, we have in this case that

$$\frac{\partial E_{in}}{\partial W^{(l)}} = \frac{1}{N}\sum_n \frac{\partial e_n}{\partial W^{(l)}} = 0$$

for $l = 1, \cdots, L$. If we use gradient descent to update the weights, we have that

$$W^{(l)} \leftarrow W^{(l)} - \eta\frac{\partial E_{in}}{\partial W^{(l)}} = W^{(l)};$$

and if we use stochastic gradient descent to update the weights, we have that

$$W^{(l)} \leftarrow W^{(l)} - \eta\frac{\partial e_n}{\partial W^{(l)}} = W^{(l)}.$$

In each case, the weights remain constant (equal to 0) which is actually something we do not want when we are searching for an optimum.

## Problem 7.12

From Problem 7.11, the gradient descent update step may be written as

$$w_{t+1} = w_t - \eta H(w_t - w^*);$$

if we substract $w^*$ from both sides, we see that

$$(w_{t+1} - w^*) = (w_t - w^*) - \eta_t H (w_t - w^*)$$
$$\Leftrightarrow \qquad \epsilon_{t+1} = \epsilon_t - \eta_t H \epsilon_t$$
$$\Leftrightarrow \qquad \epsilon_{t+1} = (I - \eta_t H)\epsilon_t$$

where $\epsilon_t = w_t - w^*$. Since $H$ is symmetric, one can form an orthonormal basis with its eigenvectors. Projecting $\epsilon_t$ and $\epsilon_{t+1}$ onto this basis, we see that in this basis, each component decouples from the others, and letting $\epsilon(\alpha)$ be the $\alpha$th component in this basis, we see that

$$\epsilon_{t+1}(\alpha) = (1 - \eta_t \lambda_\alpha)\epsilon_t(\alpha)$$

where $\lambda_\alpha$ is a positive eigenvalue of $H$ (which is positive definite). Now, by proceeding recursively and by using the Taylor expansion, we are able to write that

$$
\begin{aligned}
\epsilon_{t+1}(\alpha) &= \epsilon_1(\alpha) \prod_{i=1}^{t} (1 - \eta_i \lambda_\alpha) \\
&= \epsilon_1(\alpha) \prod_{i=1}^{t} e^{\ln(1 - \eta_i \lambda_\alpha)} \\
&= \epsilon_1(\alpha) e^{\sum_{i=1}^{t} \ln(1 - \eta_i \lambda_\alpha)} \\
&\approx \epsilon_1(\alpha) e^{\sum_{i=1}^{t} (-\eta_i \lambda_\alpha - \frac{1}{2}\lambda_\alpha^2 \eta_i^2)} \\
&\approx \epsilon_1(\alpha) e^{-\lambda_\alpha \sum_{i=1}^{t} \eta_i - \frac{1}{2}\lambda_\alpha^2 \sum_{i=1}^{t} \eta_i^2}
\end{aligned}
$$

since $\eta_t \to 0$, we have that $1 - \eta_t \lambda_\alpha > 0$. However, since $\sum_t \eta_t = +\infty$ and $\sum_t \eta_t^2 < \infty$, we get that

$$e^{-\lambda_\alpha \sum_{i=1}^{t} \eta_i} \to 0 \text{ and } e^{-\frac{1}{2}\lambda_\alpha^2 \sum_{i=1}^{t} \eta_i^2} \leq C,$$

which gives us

$$\prod_{i=1}^{t} (1 - \eta_i \lambda_\alpha) \approx \underbrace{e^{-\lambda_\alpha \sum_{i=1}^{t} \eta_i}}_{\to 0} \underbrace{e^{-\frac{1}{2}\lambda_\alpha^2 \sum_{i=1}^{t} \eta_i^2}}_{\leq C} \to 0.$$

In conclusion, we have that

$$w_{t+1}(\alpha) - w^*(\alpha) = \epsilon_1(\alpha) \prod_{i=1}^{t} (1 - \eta_i \lambda_\alpha) \to 0$$

for all $\alpha$.

## Problem 7.13

$(a)$ In general, the finite difference approximation to the first order partial derivatives of a function $f(x, y)$ is given by

$$\frac{\partial f}{\partial x} \approx \frac{f(x + h, y) - f(x - h, y)}{2h}$$

and

$$\frac{\partial f}{\partial y} \approx \frac{f(x, y + h) - f(x, y - h)}{2h}.$$

If we apply the same idea to the function $E(w_1, w_2)$, we get

$$\frac{\partial E}{\partial w_1} \approx \frac{E(w_1 + h, w_2) - E(w_1 - h, w_2)}{2h}$$

and

$$\frac{\partial E}{\partial w_2} \approx \frac{E(w_1, w_2 + h) - E(w_1, w_2 - h)}{2h}.$$

If we consider now the second order partial derivatives, we may write that

$$
\begin{aligned}
\frac{\partial^2 E}{\partial w_1^2} &\approx \frac{\frac{\partial E}{\partial w_1}(w_1 + h, w_2) - \frac{\partial E}{\partial w_1}(w_1 - h, w_2)}{2h} \\
&\approx \frac{\frac{E(w_1 + 2h, w_2) - E(w_1, w_2)}{2h} - \frac{E(w_1, w_2) - E(w_1 - 2h, w_2)}{2h}}{2h} \\
&\approx \frac{E(w_1 + 2h, w_2) + E(w_1 - 2h, w_2) - 2E(w_1, w_2)}{4h^2};
\end{aligned}
$$

and, by the same reasoning, that

$$\frac{\partial^2 E}{\partial w_2^2} \approx \frac{E(w_1, w_2 + 2h) + E(w_1, w_2 - 2h) - 2E(w_1, w_2)}{4h^2}.$$

It remains to compute the last second order partial derivative, we have that

$$
\begin{aligned}
\frac{\partial^2 E}{\partial w_1 \partial w_2} &\approx \frac{\frac{E(w_1 + h, w_2 + h) - E(w_1 - h, w_2 + h)}{2h} - \frac{E(w_1 + h, w_2 - h) - E(w_1 - h, w_2 - h)}{2h}}{2h} \\
&\approx \frac{E(w_1 + h, w_2 + h) + E(w_1 - h, w_2 - h) - E(w_1 + h, w_2 - h) - E(w_1 - h, w_2 + h)}{4h^2}.
\end{aligned}
$$

## Problem 7.14

($a$) The Lagrangian for this constrained optimization problem is

$$
\begin{aligned}
\mathcal{L} &= E_{in}(w_t) + g^T \Delta w + \frac{1}{2}\Delta w^T H_t \Delta w + \alpha(\Delta w^T \Delta w - \eta^2) \\
&= E_{in}(w_t) + g^T \Delta w + \frac{1}{2}\Delta w^T (H_t + 2\alpha I)\Delta w - \alpha\eta^2
\end{aligned}
$$

where $\alpha$ is the Lagrange multiplier.

($b$) If we solve the previous expression for $\Delta w$ and $\alpha$, we get that

$$\nabla_{\Delta w}\mathcal{L} = g_t + (H_t + 2\alpha I)\Delta w = 0,$$

which gives us

$$\Delta w = -(H_t + 2\alpha I)^{-1} g_t$$

since $H_t + 2\alpha I$ is positive definite; and also that

$$\nabla_\alpha \mathcal{L} = \Delta w^T \Delta w - \eta^2 = 0,$$

which gives us

$$\Delta w^T \Delta w = \eta^2.$$

($c$) We know that $\alpha$ satisfies the following equations

$$(H_t + 2\alpha I)\Delta w = -g_t$$
$$\Rightarrow \quad \Delta w^T (H_t + 2\alpha I)\Delta w = -\Delta w^T g_t$$
$$\Rightarrow \quad \Delta w^T H_t \Delta w + 2\alpha \underbrace{\Delta w^T \Delta w}_{=\eta^2} = -\Delta w^T g_t$$
$$\Rightarrow \quad 2\alpha\eta^2 = -\Delta w^T H_t \Delta w - \Delta w^T g_t$$
$$\Rightarrow \quad \alpha = -\frac{1}{2\eta^2}(\Delta w^T g_t + \Delta w^T H_t \Delta w).$$

## Problem 7.15

($a$) If we use the inversion formula, we immediately get that

$$H_{k+1}^{-1} = (H_k + g_{k+1}g_{k+1}^T)^{-1} = H_k^{-1} - \frac{H_k^{-1}g_{k+1}g_{k+1}^T H_k^{-1}}{1 + g_{k+1}^T H_k^{-1} g_{k+1}}.$$
